

48730-32548 Cyber Security Lab 1 (Week-2)

- Lab Environment Setup-M ac

Introduction to Lab Environment

The Virtual Machine Images for the labs will be available to download from [Google Drive](#) **make sure to access the google drive using your UTS account!** We will be using the latest version of VMware Fusion Player (Mac) only for **Intel-Based machines**, if you have a **M1 chip Mac** this will not work as they are not supported yet!

You can get the latest version of Fusion Player (Mac) for free from the VMWare website --> [Link](#)

Make an account with VMware in the above link, once that is done you will be given a license key and see an option to download the Fusion Player .dmg file. Follow the instructions and install the software to your computer granting it full access every time it prompts you.

Important: Due to multiple lab activities and use of multiple VM images, you are expected to bring your own USB/External Storage with a minimum capacity of 64GB as a backup (USB-3.0 Standard).

Important: M1 Chipset Macs are still not yet supported although Intel-based Macs are. Either switch to a Windows PC or feel free to use the Lab Computers in Building 11

Important: Depending on the specs of your computer you may encounter lagging as running 3 VM's is very taxing to your RAM. The Lab PC's work fine, as well as any Lab Computer with VMware in B11 to complete your lab activities or assessments.

To run the VM,

Step 1. Download the Server, Client & Attacker .OVA files (highlighted in blue) to your computer. Make sure to access the Google Drive link using your UTS Account (highlighted in red).

Step 1.5. You may open VMWare Fusion Player by double clicking the desktop icon or by selecting it from the menu bar at the top of your screen (Red Arrow). We can open our **Virtual Machine Library** to open the VMware interface.

Step 2. Once you have all the VM files and VMWare Fusion Player installed, follow the images and instructions as shown below to boot them. Go into your folder containing the .ova VM files, **select a VM** and **open it** (double click it). I have selected the Server VM.

Step 3.. It will then open a dialog box and you will begin to configure/ import that VM file. Select **Continue** and follow the steps until completion.

Step 3 Contd. The next step will be to give it a name and choose where to save the VM instance. You should be weary of your storage space, I am saving it to my external drive. Select **Save** once done and continue with the setup.

Step 3 Contd.. It will then go on to import the VM, once the progress bar has reached the end you have finished with the setup, select **Finish**.

Step 4. If you see a play button select it and run the VM, or the image will start to boot itself.

Step 5. When it finishes loading up, you will see the login screen of the VM. If it prompts you for access, allow it full access.

Step 6. Enter the password into the CyberSec profile and login.

The login credentials are:

Username: CyberSec

Password: cybersec

Step 7. You will finally see the Desktop and our job is done. **To open up another VM instance or all of them and have them running simultaneously, repeat steps 2 - 7.**
